"Relationship Between the Lead Content of Blood and Urine in Subjects not Exposed to Lead."

Prague, Casopis Lekaru Ceskych, Vol 105, No 30, 15 Jul 66, pp 810 - 812

Abstract /Author's English summary modified/7: Within the range of normal lead concentrations that is between 10 to 26 microgram % in the blood and 24 to 46 micrograms per liter in the urine there is a practical direct relationship. This proves that within the limits of normal lead concentrations, the lead is excreted by glomerular filtration only. 1 Figure, 1 Table, 2 Western, 3 Czech references. (Manuscript received Mar 66).

"Treatment of Chronic Bronchitis and Lung Emphysema."

Prague, Pracovni Lekarstvi, Vol 18, No 9, Nov 66, pp 406 - 414

Abstract: When chronic bronchitis is not treated, respiration insufficiency develops, which finally leads to cor pulmonale. The treatment should eliminate acute exacerbations which lead always to progressive disease. Treatment by suitable drugs is recommended; bronchodilatants, mucolytics, and antibiotics are the best. The treatment should include respiration rehabilitation and aerosol inhalations. 1 Figure, 1 Table, 18 Western, 53 Czech, 3 Russian references. (Manuscript received 23 Mar 66).

"Direct Revascularization of Myocardium Following an Experimental Infarct in Dogs"

Prague, Casopis Lekaru Českých, Vol CII, No 26, 28 June 63,  
p 725.

Abstract: Experiments lead to the following conclusions:  
1. Anastomosis between the system and coronary artery is feasible even with a pulsating heart. 2. Infarct-like changes were observed following the tying of r. interventricularis. A partial adjustment took place following anastomosis. 3. Microscopic examination showed ischemic deposits in dogs with anastomosis

p 725.

in contrast to large infarcts in dogs without anastomosis.  
4. A sudden inflow of blood into the ischemic deposit may be  
accompanied by an immediate fibrillation of chambers. It can  
be prevented by a temporary interruption of the blood flow  
by means of anastomosis and its slow and interrupted liberation.

PHASE I BOOK EXPLOITATION

POL /2574

Teisseyre, Jerzy

Problemy i perspektywy lotnictwa (Problems and Prospects of Aviation) Warszawa,  
Wiedza Powszechna, 1958. 272 p. Errata slip inserted. 5,253 copies printed.  
Ed.: Józef Kowalczyk; Tech. Ed.: Stefania Rzęcka.

PURPOSE: This book is intended for general readers and especially for young  
people who may become interested in a more extensive study of aviation.

COVERAGE: This is a popular introduction to the field of contemporary aviation,  
excluding military aviation. The book consists of 6 chapters and 4 appendixes.  
A brief outline history of the development of aviation explains the principles  
of flight and describes aircraft design and operation. One chapter  
covers international and Polish air transportation. The last chapter describes  
rocket development, satellites and future interplanetary travel. The author  
thanks the Administration of "LOT" Airlines and the Administration of the  
Experimental Gliding Institute in Bielsk for statistical data. Professors  
of the Warsaw Politechnic, J. Bukowski and Wl. Fishdon, reviewed the book  
and Mrs. Janina Wieczerska edited the text.

Title : Calibration of Rotorimeters

Orig Pub : Fomicry, automet., kontrola, 1957, 3, No 11, 425-429

Abstract : Theory and basic equations involved in the calibration of rotorimeters ( $R$ ) are presented. It is shown that the accuracy of measurements with  $R$  is attainable only when instruments are calibrated specifically for the conditions at which they actually operate. Changes in operating conditions (temperature, pressure, viscosity, and  $Ro$  values) cause changes in  $\alpha$ . The relation of  $\alpha = f(Ro)$  for  $R$ 's having different types of floats is presented in a number of graphs and in the nomogram. Description and schematic diagrams of the basic calibration systems of  $R$ , operating on gaseous mixtures are also presented. They include the use of measuring gasholders,

Title: The Conducting Half-Plane Problem in Geophysical Exploration(J)

Original  
Periodical: Acta geophys. polon., 1954, 2, No 3, 140-148; English; Polish  
resume

Abstract: In the theoretical analysis of the phenomena involved in electric prospecting using the induction method, the field produced by the transmitter loop is identified with the field of an oscillating magnetic dipole. When the continuity of the medium is disturbed, complicated diffraction fields occur. The conducting half-plane is considered as one case of such a disturbance. Since no general solution was obtained for a half-plane of finite conductivity even for the case of the plane wave, the author considers the diffraction for the case of a half-plane, having an infinite conductivity.

Card 1/3

Poland/Physics of the Earth - Geophysical Prospecting, 0-5

Abst Journal: Referat Zhur - Fizika, No 12, 1956, 36472

**Abstract:** The general solution for the magnetic dipole, which is oriented arbitrarily with respect to the half-plane, is expressed in terms of a definite integral, containing the Hankel function of the first order and of the second kind. Senior gave an approximate solution for short waves. Taking into account the conditions under which the induction method is used, the author gives an approximate solution for long waves and considers the case of a vertical half-plane. The expression for the field component is converted into a dimensionless one, by dividing the former by the value of the field in vacuum. The solution is represented in the form of a series, where for long waves one neglects the terms containing  $\chi^3$ , and the higher powers of  $\chi$  ( $\chi = kR$ , where  $k$  is the wave number and  $R$  is the distance between the loops of the instrument). Measurements in the field are carried with a constant value of  $R$ , and only the amplitude of the vertical component  $H_c$  of the field is determined, since the phase shift will be almost zero for long waves in the case of a half-plane with infinite conductivity. Calculated values of the field observed from a distance  $n = \chi/R$  from the edge of the half-plane are given. The sharp changes in the field occur at very small

Title: The Conducting Half-Plane in Geophysical Exploration (II)

Original Periodical: Acta geophys. polon., 1954, 2, No 4, 169-175; English; Polish  
resume

Abstract: In preceding work by the author (Referat Zhur - Fizika, 1956, 36472), he solved the problem of determining the magnetic field intensity, produced by an oscillating magnetic dipoles located on the earth's surface, for the case of a homogeneous medium of infinitely large resistance, containing a conducting half-plane that is perpendicular to the surface of the earth. The investigated magnetic field was broken into 2 parts -- a static and a nonstatic, and owing to the complicated computations only the intensity of the static portion of the field was determined.

Card 1/3

Poland/Physics of the Earth - Geophysical Prospecting, 0-5

Abst Journal: Referat Zhur - Fizika, No 12, 1956, 36473

**Abstract:** In the first approximation it corresponds to the intensity of the magnetic field that is measured during induction prospecting. As a result of the calculation, the author obtained an equation for determining the ratio of the measured value of the horizontal component of the magnetic field intensity to its value in vacuum. The author used this equation to determine the ratio  $\sigma$  of the measured value of the vertical component of the magnetic field intensity over a homogeneous medium of infinitely large resistance and containing a conducting half-plane parallel to the surface of the earth, to the value of the field intensity in vacuum. Curves of the variation of  $\sigma$  along the profile transverse to the face of the half-plane, calculated from this equation, at various depths of the half-plane, are given for the case of a measuring setup consisting of a transmitting and a receiving dipole. All the curves have a common flexure, corresponding to the placement of one of the dipoles over the edge of the half-plane, when the second dipole is located outside it. The values of the maxima located outside the half-plane and of the minima under it decreases sharply with increasing depth of the half-plane and can hardly be

Card 2/3

Poland/Physics of the Earth - Geophysical Prospecting, 0-5

Abst Journal: Referat Zhur - Fizika, No 12, 1956, 36473-

Abstract: discerned at a depth equal to half the distance between the dipoles. This leads to the practical conclusion that the induction method of geophysical prospecting applies only to shallow regions.

AUTHORS:

Teisseyre, Roman, and Siemek, Tadeusz

TITLE:

A new method of determining the direction of surface-wave approach and the application of this method to the microseismic measurements of the Phu-Lien Seismological Station

PERIODICAL: Acta Geophysica Polonica, vo. 8, no. 4, 1960, 312 - 323

TEXT: The direction of microseismic wave approach can be computed from the relative phase displacements shown by three seismographs, located at some distance (1 to 3 km) from each other. This method of tripartite stations is not in common use because special equipment is required. Currently there are other ways for studying the problem and for solving the problems related to surface wave sources, to the ratio of the Love to the Rayleigh components. Among recent studies those on correlation methods seem to be of special interest. The correlation coefficient of the Rayleigh and the Love waves may be used for determination of direction. The authors present in this paper a relatively simple method for comparing the approach directions. This method is based upon amplitude analysis at several time directions.

A new method of determining the direction of...

intervals. It is independent of the value of the Love wave to Rayleigh wave ratio, and changes in this ratio do not matter. The direction of approach of the Rayleigh waves coincides with that of the Love wave and both coincide with the line connecting the microseismic source with the station. This direction does not vary significantly during a relatively long time (one hour), provided that the path covered by a typhoon in that time is short in relation to the distance to the station. In a short time interval the character of the Rayleigh wave motion remains unaltered, which means that the ratio of the ellipse axes does not change. This ratio, being constant for every single period motion, varies with periods. For this reason the dependance of the ellipse's axes ratio on the wave periods must be taken into account. Stoneley made theoretical calculations of the discussed ratio at different depths, using three models of crust structure. These values can serve for a normalization of the axes ratio of different periods. The author proceeds to consider this ratio as a constant, valid for waves with near periods. Nine rules for the practical application of this method are given. On the basis of the new method calculations were made for some data of the Phu-Lien Seismological Station. The case of typhoon activity during

Some remarks on a relationship between dislocation processes and seismic activity

PERIODICAL:

Referativnyy zhurnal, Geofizika, no. 12, 1962, 20, abstract 124196 (Studii si cercetări astron. si seismol., 6, no. 2 1961, 217-220 (Eng.; summary in Rum.))

TEXT:

The difference between geologic and physical dislocations is described. A schematic model of physical dislocations within a continuous medium is given. Lines of physical dislocations are characterized by high energy concentrations in the presence of a strong field of shear deformations, which is expressed in these lines. The increase of intrinsic energy in the dislocation system results in the dislocation reaching the ground surface and causing an earthquake. In this case intrinsic energy is converted into deformation work and seismic radiation. A formula is given

Card 1/2

Some results on a relationship ...

PERIODICAL: Acta geophysica Polonica, v. 9, no. 1-2, 1961, 3 - 57

TEXT: In this paper, the author discusses the fundamentals of this theory, including a summary of the work which has already been completed. Application of dislocation theory is based on the following assumptions: 1) Dynamic processes in the earth's interior are in causal relation with the spatial distribution of shear stress field and its changes; 2) The importance between the spatial distribution of shear stress field and its changes; 3) The homogeneity forming the fields of dislocation under the action of stress and in dislocations, the stresses  $p_{23}(p)$  are uniformly distributed small contour +

$$p_{23} \stackrel{\text{def}}{=} \frac{\pi\mu}{2} \left( \frac{3}{2} - \frac{c^2}{a^2} \right) \lim(n \cdot b \cdot \rho) \quad (1.1)$$

with  $b$  - dislocation slip vector,  $\rho$  - radius of contour dislocation,  $n$  - number of dislocations per unit surface,  $\mu$  - rigidity modulus,  $a$  and  $c$  = velocities of P- and S-waves respectively. The limit is taken for  $n \rightarrow \infty$ ,  $b \rightarrow 0$ ,  $\rho \rightarrow 0$ , and the condition

$$nb\rho = \text{const.}$$

(1.2)

applies along the surface; 4) The equivalence of the crack field with a field of positive and negative dislocations in the linear case, and with a system of concentric contour dislocations for a finite closed crack. The relations between the stress field and inhomogeneities are expressed in the properties of the dislocation describing disturbances of the stress field, and depending on the structure of field and medium, the action of the field can lead to a pair of screw or edge dislocations or a contour dislocation. The basic condition for the development of dynamic processes is that

Card 2/8

24125

Dynamic and time relations ...

P/026/61/009/001/001/005  
D249/D301

the action of the external field exceeds the mutual attraction of the contour dislocation elements or of the dislocation pair. This leads simply to the inequalities

$$r_s > 0,135 \cdot 2\rho_0 \quad \text{or} \quad r_e > 0,55 \cdot 2\rho_0, \quad (2.2)$$

for screw and edge dislocations respectively, expressing the lowest limit of initial approach of dislocations at which further development of dislocation processes is possible.  $2\rho_0$  is the diameter of the elementary dislocations,  $c^2/a^2$  is taken as  $1/3$ , and the Poisson coefficient as  $1/4$ . It is assumed that the dynamic processes in the earth are related to mutual displacements of masses which may be described by the formation and motion of dislocation. This motion is given by

$$m\ddot{v} + \beta v + \delta = pb \quad (2.5)$$

where  $pb$  - force on dislocation,  $m$  - mass of dislocation (=ratio of dislocation energy to the square of the S-wave velocity for a

Card 3/8

P/026/61/009/001/001/005  
D249/D301

Dynamic and time relations ...

screw dislocation),  $\beta$  and  $\delta$  are coefficients,  $v$  ~ velocity of dislocation. If  $\delta/b =$  static strength, the dynamic strength is

$$S = \frac{mv}{b} + \frac{\beta v}{b} + \frac{\delta}{b}, \quad (2.6)$$

where  $\beta/b$  represents the coefficient of viscosity. Thus, rapid formations of a crack or dislocation requires a fairly strong external stress field and constitutes a possible earthquake category. The magnitude of the displacement  $b$ , which has a lower limit given by crystal lattice constants of  $\sim 10^{-8}$  cm and an upper limit of apparently a few cm, may easily be reconciled with the observed great displacement of masses by assuming successive addition of a number of single displacements. The deformative properties of finite contour dislocations are easily shown by the radial component of its repulsive force between two concentric dislocations with uniform orientation. The part played by structural inhomogeneities in the formation of dislocations is illustrated by considering the contact between two media in the earth as a number of nearly para-

Card 4/8

Dynamic and time relations ...

24125  
P/026/61/009/001/001/005  
D249/D301

lled small layers representing transient states. When the dislocation zone intersects this, dislocations may be formed in the contact zone as well as in the displacement zone. In considering the movement and extension fo the deformation, comparison is made between the dislocation theory and the crack theory of A.A. Griffith (Ref. 14: Phil. Trans. Roy. Soc., A221, 163, 1920) and (Ref. 15: First Inter. Cong. Appl. Mech. p. 55, Delft, 1924), which is especially suitable for the description of the formation of inhomogeneities. Using the equations of F.R.N. Nabarro (Ref. 26: Phil. Mag. 122, 1224, 1951) for the displacement field of a contour dislocation, the field of a pair of dislocations of finite length is obtained. For both screw and edge dislocation pairs, there is a distribution of nodal lines corresponding to that of a dipole pair with moments. The approach of dislocations may be described as the generation of a series of successive dislocation pairs. From equation (2.5), the approach velocity may be determined

$$v = \frac{1}{\varphi L} + \frac{\tau}{\varphi^2 L^3} + \frac{\tau^2}{\varphi^3 L^5} + \dots \quad (5.10)$$

Card 5/8

24125  
P/026/61/009/001/001/005  
D249/D301

Dynamic and time relations ...

together with relations

$$v^{\max} \approx 2.30 \frac{1}{\varphi L}, \quad v^{\max} t^{\max} \approx 1.5L \quad (5.12)$$

where  $\varphi = \frac{2\pi\beta}{\mu b^2}$ , L is the distance of the dislocation corresponding

to the beginning of the earthquake, and  $t$  the self-time of the dislocation. This process does not basically change the equations for the displacement field. The estimated deformation work during an earthquake is in good agreement with the results of P. Byerly and J. DeNoyer (Ref. 10: "Energy in Earthquakes as Computed from Geodetic Asservations" in "Contributions in Geophysics", I, 17, Pergamon Press, 1958) based on elastic rebound theory. The author concludes with a survey of the results obtained so far with the dislocation theory of earthquakes: 1) The release mechanism of the internal strain energy of the medium, the influence of inhomogeneities on the generation of the dislocations, and the part of the microdislocation in the mechanism of stress transfer are explained;

Card 6/8

24125

Dynamic and time relations ...

P/026/61/009/001/001/005  
D249/D301

2) The influence of the discontinuity surface on the process of seismic energy release is determined; 3) Good agreement with observed values of total quake energy, and between quake displacements and displacements of a pair of screw dislocations, resulting in the estimation of quake depths from surface displacements; 4) Better understanding of the features of internal deformation; 5) Approximate elucidation of the statistical laws on earthquake occurrence, and introduction of the dependence on the radius of the dislocation; 6) Estimation of the coefficients in the equation of motion of the dislocation and the formulation of a new conception of the strength problem connected with the motion, and of the velocity dislocation movements preceding the quake; 7) Equations for the contour dislocation field, the field of approaching pairs, the velocity of motion of a dislocation, the duration of a quake, etc.; 8) An elementary theory of replicas. The author thanks Professor, Doctor Tadeusz Olczak, Professor, Doctor Henryk Teisseyre, Docent, Doctor Maciej Suffczyński, and Master of Engineering Zofia Droste for valuable discussions. AUTHOR: Teisseyre, Roman

TITLE: Thermomechanical model of the earthquake origin and process

SOURCE: Acta geophysica polonica, v. 11, no. 4, 1963, 229-233

TOPIC TAGS: seismology, earthquake model, seismic model, earthquake origin, seismic energy conversion, thermodynamics

ABSTRACT: Thermoelasticity equations expressed in terms of displacement and temperature fields are developed to describe earthquake phenomena in terms of irreversible thermodynamics in a thermoelastic medium. The general concepts of thermoelasticity are applied to earthquake investigations, first, by describing the role of the thermal properties of the earth's crust and mantle in the development of tectonic processes and earthquakes, and secondly, by constructing a thermomechanical model of the physical processes occurring at the earthquake focus. The apparatus described represents partly an original contribution and partly an improvement of existing techniques for the registration of reactions of the isolated frog lung to drugs. Its advantages are as follows: Oxygenation of the Ringer solution is effected in a side-tube so that the mechanical action of bubbles on the lung is avoided; the drugs are distributed rapidly in a uniform manner; the action is of vertical type and the pressure of the writing lever is constant and adjustable. Two systems can be used simultaneously in parallel, inscribing the reactions of

3902 CONT.

the 2 lungs of the same animal on the same vertical record. With the aid of a  
clockwork mechanism functioning as a brake it is possible to regulate the rotation  
of the recording drum so that it makes only one turn in 96 hr. The apparatus can  
be used for other organs also. Graur - Bucharest

The Rumanian People's Republic.

Orig Pub : Comun. Acad. RPR, 1956, 6, No 7, 941-947

Abstract : Analysis of the fruits of various varieties of dogrose  
of the Rumanian People's Republic has determined that  
the fruits of Rosa Pendulina L. contain the maximum  
quantity of ascorbic acid -- 9510 mg. per 100 g.; in the  
second place is R. glauca Vill. (5280 mg. per 100 g.).  
Dogrose species of the Caninae section contain much less  
ascorbic acid (500-2800 mg. per 100 g.).

Orig. Pub.	:	Fiziol. norm. si patol., 1958, 5, No. 1, 21--27	
Abstract : BaCl <sub>2</sub> in concentrations of 0.3--1.2 millimoles produced a weakening of the musculature of an isolated frog lung which had been brought to a state of contraction in Ringer's solution. This effect was noted upon the tonic component of contraction, but not on the spontaneous contractile activity of the organ during stimulation. In concentrations 20--100 times higher Ba caused tonic contraction even in the weakened lung muscles.--From the author's summary.

"Considerations on the Stimulating Effects of Atropine on the  
Skeletal Musculature."

Bucharest, Revista Sanitara Militara, Vol 59, No 3, May-Jun 63,  
pp 533-536.

Abstract: Describes a study on the effects of atropine on  
the abdominal muscles of frogs and the dorsal muscles of leeches.  
Atropine in concentrations  $3 \times 10^{-17}$  to  $3 \times 10^{-5}$  was found to  
produce contraction of the striated musculature, and that anti-  
cholinesterase potentiates the contracting effects of atropine  
on the striated musculature.

547. THE VALUE OF YOUNMANS' EGG YOLK MEDIUM USED FOR LABORATORY DIAGNOSIS OF TUBERCULOSIS - Valoarea mediului Youmans cu galbenus de ou, folosit la înșămînările de diagnostic în tuberculoză - Teitel M., Kern L. and Constantin St. - FTIZIOLOGIA 1957, 6/6 (540-553) Graphs 3

The authors recommend a culture medium which is prepared from ingredients that are easily procured. It is a medium of Youmans type, with 10% egg yolk. Using this medium, practically the same results were obtained as with the conventional media, viz.: on Loewenstein medium 73% cultures, on Youmans with ox serum 64% cultures, and on Youmans medium with egg yolk 58% cultures.
